EasyXpress™ Large-Scale Synthesis Handbook

EasyXpress Protein Synthesis Mega Kit

EasyXpress NMR Protein Synthesis Kits

For large-scale production of proteins by in vitro translation for structural analysis
Trademarks: QIAGEN®, QIAprep®, EasyXpress™, HiSpeed® (QIAGEN Group).

Strep-tag™ and Strep-Tactin™ (IBA GmbH)

Registered names, trademarks, etc. used in this document, even when not specifically marked as such, are not to be considered unprotected by law.

Strep-tag technology for protein purification and detection is covered by US patent 5,506,121, UK patent 2272698 and French patent 93 13 066; Strep-Tactin is covered by US patent 6,103,493.

Procedures for production of a protein containing seleno-methionine suitable for structure determination by crystallography and X-ray analysis may require a license under United States patent application US 2002/168705 or a subsequently granted patent or corresponding intellectual property.

</tbody>
</table>

When stored under the above conditions and handled correctly, both kits can be stored for at least 6 months without showing any reduction in performance.

**Safety Information**

When working with chemicals, always wear a suitable lab coat, disposable gloves, and protective goggles. For more information, please consult the appropriate material safety data sheets (MSDSs). These are available online in convenient and compact PDF format at www.qiagen.com/ts/msds.asp where you can find, view, and print the MSDS for each QIAGEN kit and kit component.

**24-hour emergency information**

Emergency medical information in English, French, and German can be obtained 24 hours a day from:

Poison Information Center Mainz, Germany, Tel: +49-6131-19240

**Quality Control**

In accordance with QIAGEN’s ISO-certified Total Quality Management System, each lot of EasyXpress Kits is tested against predetermined specifications to ensure consistent product quality.
Product Use Limitations

EasyXpress kits are developed, designed, and sold for research purposes only. It is not to be used for human diagnostic or drug purposes or to be administered to humans unless expressly cleared for that purpose by the Food and Drug Administration in the USA or the appropriate regulatory authorities in the country of use. All due care and attention should be exercised in the handling of many of the materials described in this text.

Product Warranty and Satisfaction Guarantee

QIAGEN guarantees the performance of all products in the manner described in our product literature. The purchaser must determine the suitability of the product for its particular use. Should any product fail to perform satisfactorily due to any reason other than misuse, QIAGEN will replace it free of charge or refund the purchase price. We reserve the right to change, alter, or modify any product to enhance its performance and design. If a QIAGEN product does not meet your expectations, simply call your local Technical Service Department or distributor. We will credit your account or exchange the product — as you wish.

A copy of QIAGEN terms and conditions can be obtained on request, and is also provided on the back of our invoices. If you have questions about product specifications or performance, please call QIAGEN Technical Services or your local distributor (see inside back cover).

Technical Assistance

At QIAGEN we pride ourselves on the quality and availability of our technical support. Our Technical Service Departments are staffed by experienced scientists with extensive practical and theoretical expertise in molecular biology and the use of QIAGEN® products. If you have any questions or experience any difficulties regarding EasyXpress kits or QIAGEN products in general, please do not hesitate to contact us.

QIAGEN customers are a major source of information regarding advanced or specialized uses of our products. This information is helpful to other scientists as well as to the researchers at QIAGEN. We therefore encourage you to contact us if you have any suggestions about product performance or new applications and techniques.

For technical assistance and more information please call one of the QIAGEN Technical Service Departments or local distributors (see inside back cover).
Introduction

In vitro translation is a widely used tool for the production of recombinant proteins that can be used for a wide variety of downstream applications, including activity assays, protein–protein interaction studies, the expression and analysis of open reading frames, and structural and mutational analysis. Larger scale in vitro translation reactions provide unique possibilities for rapid production of large amounts of recombinant proteins suitable for a range of downstream applications, including structural analysis. To address these issues, QIAGEN has developed EasyXpress products for large scale production of up to 5 mg of recombinant protein.

The effective incorporation of stable-isotope–labeled amino acids into in vitro synthesized proteins allows structural determination in solution by high-resolution NMR spectroscopy (1–3). The EasyXpress NMR Protein Synthesis Kit allows incorporation of the stable-isotope–labeled amino acids threonine, arginine, valine, serine, or lysine. Labeling of these amino acids minimizes isotope scrambling effects (distribution of isotopic label to other amino acids due to amino acid metabolism). Fifteen further EasyXpress NMR Kits are available for incorporation of any of the remaining 15 amino acids with an isotopic label. It should be noted that although the EasyXpress E. coli Extract production procedure drastically reduces amino acid metabolism under in vitro expression conditions (compared with the in vivo situation), a residual metabolizing activity may be observed in isolated cases, which may lead to a certain degree of isotope scrambling.

The EasyXpress Protein Synthesis Mega Kit allows rapid production of milligram quantities of recombinant protein for a wide range of applications, including comprehensive functional studies, aptamer selection studies, and animal immunization. In addition, the kit allows incorporation of the unnatural amino acid selenomethionine. The incorporation of the unnatural, cytotoxic amino acid selenomethionine into in vitro synthesized proteins facilitates phasing of crystal protein structures and atomic structure determination using X-ray crystallography (3, 4).

The EasyXpress System

EasyXpress Mega and NMR Kits use highly productive E. coli lysates, which contain all translational machinery components (i.e., ribosomes, ribosomal factors, tRNAs, aminoacyl-tRNA synthetases, etc.) as well as T7 RNA polymerase. It is a coupled transcription–translation system that can be used to express full-length proteins from T7 or E. coli promoters in a batch reaction using supercoiled DNA templates.
Large-Scale Protein Synthesis for Structural Proteomics Projects

To generate preparative yields of protein, the high-molecular–weight translation components in the reaction are recycled after a 1-hour batch synthesis and used in a second 1-hour batch synthesis (see flowchart, page 14). The recycling procedure is performed using a gel-filtration column. During the recycling step, low-molecular–weight reaction components (e.g., inorganic phosphate) that inhibit the in vitro translation reaction are removed from the high-molecular–weight translation components. Before the second in vitro translation reaction, the recycled high-molecular–weight translation components are supplemented with missing components, such as energy providers and amino acids. The short (in contrast to other [semi-]continuous systems) reaction time of 2 hours delivers high-quality proteins and reduces detrimental effects, such as degradation or precipitation. In addition, the short reaction time minimizes isotope exchange and breakdown or metabolism of isotopically labeled amino acids.

The EasyXpress Mega and NMR Protein Synthesis Kits yield up to 5 mg soluble recombinant protein from a reaction volume of 2 x 5 ml. Before using the EasyXpress Mega or NMR Protein Synthesis Kit, we recommend evaluating a plasmid expression template’s suitability to produce soluble protein in high yields in a small-scale test reaction using the EasyXpress Protein Synthesis Mini or Maxi Kit. The relative protein yield (mg protein/ml reaction) typically increases by a factor of 2 in a large-scale reaction.

Although the EasyXpress system has been developed to give the highest yields of active and soluble protein, it may be possible to further optimize the synthesis procedure for individual proteins, e.g., the total expression or the solubility may be increased by including additives in the synthesis reaction (see EasyXpress Protein Synthesis Workflow, page 11, and Appendix A, page 38).
Workflow for Large-Scale Synthesis of Recombinant Protein Using the EasyXpress NMR or Mega Kit

1. **Template generation** (~5.5 hours) (Optional)
   - EasyXpress Linear Template Kit

2. **Small-scale IVT reaction for template evaluation** (recommended)
   - EasyXpress Protein Synthesis Mini/Maxi Kit

3. **Large-scale preparative reaction** (~2.5 hours)
   - EasyXpress Protein Synthesis Mega Kit
   - EasyXpress NMR Protein Synthesis Kits

4. **Protein purification** (~1.5 hours)
   - Ni-NTA Superflow or Agarose
   - Strep-Tactin Superflow
DNA Templates

EasyXpress kits can be used to express proteins from a variety of DNA templates, as long as they contain a T7 or other strong *E. coli* promoter (e.g., T5) upstream from the coding sequence and a ribosome binding site. We recommend using supercoiled DNA plasmids as expression vectors. Vectors such as pET3d (Novagen) are a suitable basis for generating expression constructs.

Plasmid DNA

T7 promoter-based constructs, including the pET plasmid series (Novagen), are a suitable basis for generating expression constructs. Such vectors provide mRNA-stabilizing secondary structures in the 5' and 3' untranslated regions that play an important role in increasing the efficiency of expression.

Suitable vectors are not restricted to T7 promoter-based constructs. QIAGEN’s pQE vectors have also been used successfully with EasyXpress *E. coli*-based kits.

Before use in a large-scale reaction, each expression vector should be tested in small-scale reactions (see page 38) to ensure efficient protein synthesis. The following table gives an overview of which vectors have successfully been used with EasyXpress kits.

* Expression construct kindly provided by Michael Blind, NascaCell IP GmbH, Munich, Germany.
† Available from QIAGEN Technical Service departments upon request. This vector is also suitable for cloning PCR templates generated using the EasyXpress Linear Template Kit.
Purification of plasmid DNA expression templates

Greatest yields of protein are obtained using template DNA of the highest purity. High-purity plasmid DNA can easily be obtained with the QIAGEN HiSpeed®, QIAfilter, and QIAGEN Plasmid Kits. DNA prepared using the standard alkaline lysis method described by Sambrook, Fritsch and Maniatis (5) may be sufficiently pure, but DNA must be free of RNases.

For EasyXpress Mega and NMR protein synthesis reactions, the concentration of plasmid DNA in each 5 ml in vitro translation reaction should be 10 nM, which corresponds to 100 µg of a 3 kb plasmid.
EasyXpress Large-Scale Procedure

Initial in vitro protein synthesis reaction in 10 ml tube

Removal of low-molecular-weight inhibitors by gel filtration

Add Feeding Solution and Energy Mix

Second in vitro protein synthesis reaction in 50 ml tube

Purification, e.g., using Ni-NTA Superflow (not supplied)

Pure recombinant protein
Purification of In Vitro-Synthesized Proteins

In vitro-synthesized proteins that carry a 6xHis tag or Strep-tag™ can be easily purified using Ni-NTA Superflow or Strep-Tactin™ Superflow respectively. For downstream applications demanding ultrapure protein preparations, proteins carrying both tags (His·Strep-tagged proteins) can be purified using a Ni-NTA matrix followed by a second purification using a Strep-Tactin matrix. For purification protocols, see page 31.

Purification of tagged proteins using the 6xHis-tag–Ni-NTA interaction

His-tagged protein purification is based on the remarkable selectivity and high affinity of patented Ni-NTA (nickel-nitrilotriacetic acid) resin for proteins containing an affinity tag of six consecutive histidine residues — the 6xHis tag. NTA, which has four chelation sites for nickel ions, binds nickel more tightly than metal-chelating purification systems that only have three sites available for interaction with metal ions. The extra chelation site prevents nickel-ion leaching; providing a greater binding capacity, and high-purity protein preparations (6, 7). Figure 1 shows SDS-PAGE analysis of column fractions obtained from the purification of two 6xHis-tagged proteins, EF-Ts and hTNF-alpha, which were expressed using the EasyXpress Protein Synthesis Mega Kit.

Purification using the Strep-tag–Strep-Tactin interaction

The Strep-tag allows affinity chromatography on immobilized Strep-Tactin under physiological conditions. Strep-tag II is a short peptide (8 amino acids, WSHPQFEK), which binds with high selectivity to Strep-Tactin, an engineered streptavidin. The binding affinity of the Strep-tag to Strep-Tactin (Kd = 1 µM) is nearly 100 times higher than to streptavidin. After a short washing step, gentle elution of purified recombinant protein is performed by addition of low concentrations (2.5 mM) of biotin or desthiobiotin. Desthiobiotin is an inexpensive, reversibly binding, and stable analog of biotin, the natural ligand of streptavidin.

Two-step affinity purification of His·Strep-tagged proteins

The initial step of His·Strep-tagged protein purification is based on the proven 6xHis-tag Ni-NTA interaction. After elution from a Ni-NTA matrix using imidazole, recombinant proteins (which also carry the Strep-tag II epitope) are loaded directly onto a Strep-Tactin Matrix. Protein is eluted from the Strep-Tactin matrix using either biotin or desthiobiotin. This two-step affinity purification delivers ultrapure (>98% pure) protein.
Figure 1 6xHis-tagged EF-Ts and human TNF-alpha were synthesized using the EasyXpress Protein Synthesis Mega Kit and purified under native conditions from the second synthesis reaction using Ni-NTA Superflow. EF-Ts and TNF-α were synthesized using the pIX 2.0 and TAGZyme pQE-2 vectors respectively. Protein was visualized using Coomassie® Stain. C: Crude lysate; F: Flow-through fraction; W: Wash fractions.
Protocol: Large-Scale Protein Synthesis Using the EasyXpress Protein Synthesis Mega Kit

This protocol is suitable for the large-scale in vitro production of unlabeled recombinant proteins (using the supplied methionine solution) from plasmid DNA in a two-stage procedure. It can also be used for production of selenomethionine-labeled proteins (selenomethionine must be supplied by the user, see below).

Materials and reagents to be supplied by the user

- Plasmid DNA expression template encoding the protein of interest. The plasmid must contain a T7 or other strong E. coli promoter and a ribosome binding site (see page 12)
- Optional: Selenomethionine (e.g., Sigma cat. no. S3132)
- Shaking water bath
- Optional: QIArack (cat. no. 19015)

Important points before starting

- The in vitro translation system is extremely sensitive to nuclease contamination. Always wear gloves and use RNase- and DNase-free reaction tubes and filter pipet tips.
- E. coli extracts are provided as 2 individual aliquots in single tubes. Once thawed, use E. coli extract within 4 hours.
- Except for the actual transcription-translation incubation and the recycling procedure with the gel filtration column, all handling steps should be carried out on ice.
- The recommended incubation temperature for protein synthesis is 37°C, but lower incubation temperatures may improve protein solubility in some cases.
- For protein synthesis reactions, it is important to follow the order of addition for each component given in the protocol and tables.
- Do not use glass pipets at any stage of the procedure.

Procedure

Initial in vitro synthesis reaction

1. Thaw and store E. coli Extract (Mega), Methionine, Feeding Solution (Mega), and Energy Mix on ice. Thaw RNase-free Water and Equilibration/Elution Buffer at room temperature (15–25°C).
2. Thaw Reaction Buffer (–Methionine) in the supplied 12 ml plastic tube on ice and vortex thoroughly.

3. Add 100 µl of a 60 mM solution of Methionine (green screw-cap) or selenomethionine (not supplied) to the Reaction Buffer in the 12 ml plastic tube.
   The 12 ml tube will serve as the reaction vessel for the initial protein synthesis reaction.

4. Add 50 pmol of plasmid DNA expression template to the Reaction Buffer.
   This corresponds to a final concentration of 10 nM (100 µg of a 3 kb plasmid) in the final 5 ml reaction volume.

5. Make up the reaction volume to 3.25 ml with RNase-free Water.
   Use the pipetting scheme in Table 1 to calculate the required volume. It is important to follow the order of addition given in the table.

6. Add 1.75 ml E. coli Extract (Mega) to the reaction.
   Important: Do not use a glass pipet to transfer the E. coli extract as reaction components may adhere to the glass surface.

7. Gently mix the reaction by pipetting up and down.

8. Incubate the reaction in a water-bath at 37°C with gentle shaking for 1 h.

</table>
Recycling the components of the initial synthesis reaction
Steps 9–13 can be performed at room temperature (15–25°C).

9. During the protein synthesis reaction, prepare and equilibrate a Gel Filtration Column. Unscrew and remove the bottom closure and peel off the top seal. Allow the storage buffer to drain out. Equilibrate the column by applying 3 x 17 ml aliquots of Equilibration Buffer and allowing the buffer to flow through the column.
   The column can be placed in a QIArack during equilibration.

10. After 1 h incubation (step 8), centrifuge the tube containing the protein synthesis reaction at 10,000 x g for 3 min.
    This centrifugation separates precipitates and insoluble target protein.

11. Carefully pipet the entire supernatant from step 10 onto the equilibrated Gel Filtration Column.
    **Important:** Do not use a glass pipet to transfer the supernatant as reaction components may adhere to the glass surface.

12. After the supernatant has entered the column, pipet 1 ml Equilibration/Elution Buffer onto the column. Discard the flow-through fraction.

13. Place a 50 ml Reaction Flask (supplied) under the column and pipet 7 ml Equilibration/Elution Buffer onto the column. Collect the flow-through fraction in the Reaction Flask.
    This reaction flask will serve as the reaction vessel for the second protein synthesis reaction. The flow-through fraction contains the recycled high-molecular–weight reaction components.
Second in vitro synthesis reaction

14. Add 200 µl of a 60 mM solution of Methionine (green screw-cap) or selenomethionine (not supplied) to the protein synthesis reaction (flow-through fraction from step 13).

15. Thoroughly vortex the tube containing Feeding Solution (Mega) and add 1700 µl to the protein synthesis reaction.
   There may be a precipitate visible in the tube containing Feeding Solution. This will not adversely affect the reaction.

16. Add 1100 µl Energy Mix (red screw-cap) to the protein synthesis reaction.

17. Gently mix the reaction by pipetting up and down.
   Table 2 summarizes the components of the second synthesis reaction. It is important to follow the order of addition given in the table.

18. Incubate the reaction in a water-bath at 37°C with gentle shaking for 1 h.

Protocol: Large-Scale Protein Synthesis Using the EasyXpress NMR Protein Synthesis Kit

This protocol is suitable for the in vitro production of recombinant isotopically labeled proteins from plasmid DNA using the EasyXpress NMR Protein Synthesis Kit in a two-stage procedure. Proteins are labeled by the addition of isotopically labeled amino acids to the protein synthesis reaction. The supplied Amino Acid Mix (NMR) contains all required amino acids except threonine, arginine, valine, serine, and lysine. These amino acids are supplied individually and can therefore be added to the master mix in a labeled or unlabeled form.

For large-scale protein synthesis using other single amino acid substitution kits (EasyXpress NMR Protein Synthesis Kit – X, where X = Ala, Cys, Asp, Glu, Phe, Gly, His, Ile, Leu, Met, Asn, Pro, Gln, Trp, or Tyr) use the protocol on page 26.

Materials and reagents to be supplied by the user

- Plasmid expression DNA template encoding the protein of interest. The plasmid must contain a T7 or strong E. coli promoter and a ribosome binding site (see page 12)
- Isotopically labeled threonine, arginine, valine, serine, or lysine
- Shaking water bath
- Optional: QIArack (cat. no. 19015)

Important points before starting

- The in vitro translation system is extremely sensitive to nuclease contamination. Always wear gloves and use RNase- and DNase-free reaction tubes and filter pipet tips.
- E. coli extracts are provided as 2 individual aliquots in single tubes. Once thawed, use E. coli extract within 4 hours.
- Except for the actual transcription-translation incubation and the recycling procedure with the gel filtration column, all handling steps should be carried out on ice.
- The recommended incubation temperature for protein synthesis is 37°C, but lower incubation temperatures may improve protein solubility in some cases.
- For protein synthesis reactions, is important to follow the order of addition for each component given in the protocol and tables.
- Do not use glass pipets at any stage of the procedure.
Procedure

Preparation of amino acid mix

1. Thaw Amino Acid Mix (NMR) and the individual amino acids that will form the master mix.
2. Dissolve isotopically labeled amino acids in RNase-free water to give a concentration of 240 mM.
3. Add 85 µl of each missing amino acid (labeled or unlabeled) to each vial of Amino Acid Mix (NMR).
   Table 3 shows a pipetting scheme for a typical master mix.

Table 3. Amino Acid Master Mixes for Unlabeled and $^{13}$C Threonine Labeled Protein Synthesis Reactions

Initial in vitro synthesis reaction

4. Thaw and store E. coli Extract (NMR), Feeding Solution (NMR), and Energy Mix on ice. Thaw RNase-free Water and Equilibration/Elution Buffer at room temperature (15–25°C).
5. Thaw Reaction Buffer without amino acids in the supplied 12 ml plastic tube on ice and vortex thoroughly.
   The 12 ml tube will serve as the reaction vessel for the initial protein synthesis reaction.
6. Thoroughly vortex the amino acid master mix prepared in step 3. Add 500 µl amino acid master mix to the Reaction Buffer in the 12 ml plastic tube. Store the remaining amino acid master mix on ice. There may be some precipitate in the amino acid master mix. This will not affect the performance of the kit.

7. Add 50 pmol of plasmid DNA expression template to the reaction. This corresponds to a final concentration of 10 nM (100 µg of a 3 kb plasmid) in the final 5 ml reaction volume.

8. Make up the reaction volume to 3.25 ml with RNase-free Water. Use the pipetting scheme in Table 4 to calculate the required volume. It is important to follow the order of addition given in the table.

9. Add 1.75 ml E. coli Extract (NMR) to the reaction. Important: Do not use a glass pipet to transfer the E. coli extract as reaction components may adhere to the glass surface.

10. Gently mix the reaction by pipetting up and down.

11. Incubate the reaction in a water-bath at 37°C with gentle shaking for 1 h.

Recycling the components of the initial synthesis reaction

Steps 12–16 can be performed at room temperature (15–25°C).

12. **During the protein synthesis reaction, prepare and equilibrate a Gel Filtration Column.** Unscrew and remove the bottom closure and peel off the top seal. Allow the storage buffer to drain out. Equilibrate the column by applying 3 x 17 ml aliquots of Equilibration Buffer and allowing the buffer to flow through the column.
The column can be placed in a QIArack during equilibration.

13. **After 1 h incubation (step 11), centrifuge the tube containing the protein synthesis reaction at 10,000 x g for 3 min.**
This centrifugation separates precipitates and insoluble target protein.

14. **Carefully pipet the entire supernatant from step 13 onto the equilibrated Gel Filtration Column.**
**Important:** Do not use a glass pipet to transfer the supernatant as reaction components may adhere to the glass surface.

15. **After the supernatant has entered the column, pipet 1 ml Equilibration/Elution Buffer onto the column. Discard the flow-through fraction.**

16. **Place a 50 ml Reaction Flask (supplied) under the column and pipet 7 ml Equilibration/Elution Buffer onto the column. Collect the flow-through fraction in the Reaction Flask.**
This reaction flask will serve as the reaction vessel for the second protein synthesis reaction. The flow-through fraction contains the recycled high-molecular-weight reaction components.
Second in vitro synthesis reaction

17. Thoroughly vortex the amino acid master mix remaining from step 6. Add 1 ml of the amino acid master mix to the protein synthesis reaction (flow-through fraction from step 16).
There may be a precipitate visible in the tube containing amino acid master mix. This will not adversely affect the reaction.

18. Vortex the tube containing Feeding Solution (NMR) and add 900 µl to the protein synthesis reaction.

19. Add 1100 µl Energy Mix (red screw-cap) to the protein synthesis reaction.

20. Gently mix the reaction by pipetting up and down.
Table 5 summarizes the components of the second synthesis reaction. It is important to follow the order of addition given in the table.

21. Incubate the reaction in a water-bath at 37°C with gentle shaking for 1 h.

Protocol: Large-Scale Protein Synthesis Using EasyXpress Single Amino Acid Substitution NMR Kits

This protocol is suitable for the in vitro production of recombinant isotopically labeled proteins from plasmid DNA using the EasyXpress NMR Protein Synthesis Kits – X (where X = Ala, Cys, Asp, Glu, Phe, Gly, His, Ile, Leu, Met, Asn, Pro, Gln, Trp, or Tyr). Proteins are labeled by the addition of isotopically labeled amino acids to the protein synthesis reaction. The supplied Amino Acid Mix (NMR) contains all required amino acids except that indicated by the kit’s name. Isotopically labeled versions of these amino acids must be supplied by the user.

For large-scale protein synthesis using the EasyXpress NMR Protein Synthesis Kit (cat. no. 32526) use the protocol on page 21.

Materials and reagents to be supplied by the user

- Plasmid expression DNA template encoding the protein of interest. The plasmid must contain a T7 or strong E. coli promoter and a ribosome binding site (see page 12)
- Isotopically labeled amino acid
- Shaking water bath
- Optional: QIArack (cat. no. 19015)

Important points before starting

- The in vitro translation system is extremely sensitive to nuclease contamination. Always wear gloves and use RNase- and DNase-free reaction tubes and filter pipet tips.
- E. coli extracts are provided as 2 individual aliquots in single tubes. Once thawed, use E. coli extract within 4 hours.
- Except for the actual transcription-translation incubation and the recycling procedure with the gel filtration column, all handling steps should be carried out on ice.
- The recommended incubation temperature for protein synthesis is 37°C, but lower incubation temperatures may improve protein solubility in some cases.
- For protein synthesis reactions, is important to follow the order of addition for each component given in the protocol and tables.
- Do not use glass pipets at any stage of the procedure.
Procedure

Preparation of amino acid mix

1. Thaw Amino Acid Mix (without indicated amino acid).
2. Dissolve isotopically labeled amino acid in RNase-free water to give a concentration of 48 mM.
   Due to the low solubility of some amino acids, the solution may remain cloudy. This will not affect the overall performance of the reaction.
3. Carefully vortex the isotopically labeled amino acid solution and pipet 425 µl into each vial of Amino Acid Mix thawed in step 1.
   Table 6 shows a pipetting scheme for a typical master mix prepare with isotopically labeled tyrosine.

Purifying Affinity-Tagged Proteins

Recombinant proteins carrying a 6xHis- or Strep-tag can be efficiently purified in a one-step affinity purification procedure using Ni-NTA or Strep-Tactin Superflow respectively. Recombinant proteins carrying both tags (His·Strep-tagged proteins) can be purified in a two-step procedure using first Ni-NTA and subsequently Strep-Tactin Superflow. Purification can be carried out either at 2–8°C or at room temperature (15–25°C).

Purifying 6xHis-tagged proteins using Ni-NTA Superflow

This protocol can be used for purifying up to 15 mg 6xHis- or His·Strep-tagged protein generated in an EasyXpress in vitro protein synthesis reaction.

Materials and reagents to be supplied by the user

- EasyXpress in vitro protein synthesis reaction containing 6xHis-tagged target protein
- Ni-NTA Superflow Column (QIAGEN cat. no. 30622)
- Binding, wash, and elution buffers
- Microcentrifuge tubes for elution fractions
- Optional: QIArack (QIAGEN cat. no. 19015)

Buffer compositions can be found in the appendix, page 39.

Procedure

1. Centrifuge the protein synthesis reaction at 10,000 x g for 3 min at 15–25°C to precipitate insoluble material.

2. Break the seal at the outlet of a Ni-NTA Superflow column and remove the screw cap.

   Ni-NTA Superflow Columns should be stored vertically. Before opening, ensure that the Ni-NTA Superflow resin is contained in the lower narrow part of the column. If this is not the case, resuspend the resin by gently shaking the column, and keeping it in an upright position until the resin has settled.

3. Place the opened column in a rack and allow the storage buffer to drain out.

   The column will not run dry.

4. Equilibrate the column by pipetting 10 ml Buffer NPI-10 onto it and allowing the buffer to drain out.
5. Pipet the supernatant from step 1 into a clean 25 ml tube and add 10 ml Buffer NP-10. Pipet the diluted reaction onto the equilibrated Ni-NTA Superflow Column and allow the buffer to drain out. Collect and retain the flow-through fraction for subsequent SDS-PAGE analysis.

6. Wash the column by pipetting 10 ml Buffer NPI-20 onto it and allowing the buffer to drain out. Collect and retain the wash fraction for subsequent SDS-PAGE analysis.

7. Place a clean microcentrifuge tube under the column outlet and pipet 1 ml Buffer NPI-250 onto the column. Collect and label the fraction.

8. Repeat step 7 five times to give six elution fractions.

9. Analyze the flow-through, wash, and elution fractions by SDS-PAGE.
Purifying Strep-tagged proteins using Strep-Tactin Superflow

This protocol can be used for purifying up to 5 mg Strep- or His-Strep-tagged protein generated in an EasyXpress in vitro protein synthesis reaction.

Materials and reagents to be supplied by the user
- EasyXpress in vitro protein synthesis reaction or Ni-NTA Superflow elution fractions containing Strep-tagged target protein
- Strep-Tactin Superflow (QIAGEN cat. no. 30003)
- Polypropylene Columns (5 ml) (QIAGEN cat. no. 34964)
- Wash and elution buffers
- Microcentrifuge tubes for elution fractions
- Optional: QIArack (QIAGEN cat. no. 19015)

Buffer compositions can be found in the appendix, page 26.

Procedure
1. Centrifuge the protein synthesis reaction at 10,000 x g for 3 min at 4°C to precipitate insoluble material. If using Ni-NTA Superflow elution fractions, pool the fractions.
2. Resuspend 5 ml Strep-Tactin Superflow and pour into a 5ml polypropylene column.
3. Place the opened column in a rack and allow the storage buffer to drain out.
   The column will not run dry.
4. Equilibrate the column by pipetting 2 x 5 ml Buffer NP onto it and allowing the buffer to drain out.
5. Pipet the supernatant or pooled elution fractions from step 1 onto the equilibrated Strep-Tactin Superflow Column and allow the buffer to drain out.
   Collect and retain the flow-through fraction for subsequent SDS-PAGE analysis.
6. Wash the column by pipetting 2 x 5 ml Buffer NP onto it and allowing the buffer to drain out. Repeat the wash with a further 2 x 5 ml Buffer NP.
   Collect and retain the wash fractions for subsequent SDS-PAGE analysis.
7. Place a clean microcentrifuge tube under the column outlet and pipet 1.25 ml Buffer NPB onto the column. Collect and label the fraction.
8. Repeat step 7 five times to give six elution fractions.
9. Analyze the flow-through, wash, and elution fractions by SDS-PAGE.
# Troubleshooting Guide

This troubleshooting guide may be helpful in solving any problems that may arise. The scientists in QIAGEN Technical Services are always happy to answer any questions you may have about either the information and protocol in this handbook or molecular biology applications (see back page for contact information).

## Comments and suggestions

### No target protein

| a) Poor quality or wrong quantity of DNA template | Check the concentration, integrity, and purity of the DNA template. Before large-scale reactions are performed, we recommended checking DNA quality and functionality and developing optimized reaction conditions using small-scale reactions using the EasyXpress Mini or Maxi kit. The physical make-up of the construct can be optimized using linear expression templates generated using the QIAGEN EasyXpress Linear Template Kit. Prepare high-purity plasmid DNA with QIAGEN plasmid kits. |
| b) DNA template not optimally configured, or error in cloning | Check the sequence. Make sure that the start codon is in the right position for expression. Ensure that the expression plasmid contains a T7 promoter or a strong *E. coli* promoter and a ribosome binding site. See page 8 for recommendations for suitable expression constructs. |
| c) In vitro transcription or in vitro translation is disrupted by expressed protein | In small-scale reactions using the EasyXpress Mini or Maxi Kit, express the control protein EF-Ts alone and in the presence of the target protein. If expression of EF-Ts is inhibited by the presence of the target protein, it may not be possible to efficiently express the target protein using the EasyXpress Protein Synthesis System. |
| d) Amino acid master mix prepared incorrectly | Ensure that the amino acid master mix contains all 20 amino acids (labeled or unlabeled). |
Comments and suggestions

e) Rigid secondary structures in the mRNA inhibit initiation of translation

Perform small-scale control expression reactions using the EasyXpress Mini or Maxi Kit. Include an affinity-tag coding sequence at the 5' end of the protein coding sequence. If the protein to be expressed already contains a tag, move the tag to the opposite terminus.

Low expression yield

a) Poor quality or wrong quantity of DNA template.

Check the concentration, integrity, and purity of the DNA template.

Before large-scale reactions are performed, we recommended checking DNA quality and functionality and developing optimized reaction conditions using small-scale reactions using the EasyXpress Mini or Maxi Kit.

The physical make-up of the construct can be optimized using linear expression templates generated using the QIAGEN EasyXpress Linear Template Kit.

Prepare high-purity plasmid DNA with QIAGEN plasmid kits.

In small-scale reactions, determine the optimal amount of DNA template used in the in vitro translation by titration.

b) Template not optimally configured

Evaluate the level of expression of soluble protein using the EasyXpress Protein Synthesis Mini Kit.

Adding an affinity tag to the construct may increase yields and/or solubility (8). Conduct trials to find an optimal expression construct using the EasyXpress Protein Synthesis Mini Kit and EasyXpress Linear Template Kit.

See page 8 for recommendations for suitable expression constructs.

Appendix A: Optimization of EasyXpress Small-Scale Reactions

Although the EasyXpress system has been developed to give the highest yields of active and soluble protein, it may be possible to further optimize the synthesis procedure for individual proteins, i.e., the total expression or the solubility may be increased by including additives in the synthesis reaction.

As the response to additives is protein-dependent, no general recommendation can be provided. Conditions that give improved results in small-scale reactions should then be transferred linearly to the large-scale reaction (e.g., final additive concentrations showing a positive effect in small-scale reactions should be maintained in the large-scale reaction). It is important that the total volume of the large-scale reactions does not exceed 5.25 ml (first round of synthesis) and 10.5 ml (second round of synthesis) after addition of additives. The table below gives some examples of reagents and reaction conditions that may be lead to improved results with regard to protein solubility and/or yield.
